## Geomagnetic Observation Results 2003-2004

### Terra Nova Bay - Antarctica

#### **Introduction**

This report deals with activities undertaken at the Antarctic Italian Geomagnetic Observatory during the austral summer 2003-2004.

The coordinates of the Observatory at OASI are the following:

Geographic latitude:	74.6936°S
Geographic longitude:	164.0975°E
Corrected Geomagnetic latitude (IGRF00):	80.00°S
Corrected Geomagnetic longitude (IGRF00):	306.94°E
Magnetic local time midnight:	08:11 UT

This report describes the activities performed from November 9, 2003 to December 3, 2004.

For the present work H, D and Z INTERMAGNET formatted data from the fluxgate magnetometer have been used.

The proton precession magnetometers used to record F total values were Overhauser type; for a description of instruments we refer to geomagnetism text books, for example Parkinson (1983) and Wienert (1970).

Since the total intensity F time variations, at polar latitudes, where values of inclination is almost 90°, are very close to the vertical component Z time variations, the plots of total intensity time variations are not shown. They can however be obtained from the well known equation:

$$F^2 = H^2 + Z^2$$

#### **Absolute measurements**

For the normal absolute measurements-taking at the Observatory, a standard fluxgate magnetometer theodolite for the determination of D, I angles has been used.

At OASI three different azimuth marks are available, for the computation of the Declination (please refer to the 2001/2002 report for details). The coordinates of geodetic points (mark piers and measuring location) were established on the basis of GPS measurements. From these coordinates the azimuth values 152° 44' 04", 60° 13' 36" and 338° 07' 59" were found.

The proton magnetometer recordings, continuously undertaken during the execution of the DI measurements, have allowed the calculation of the absolute intensive elements.

Table 1 shows absolute measurement values for each element; the values of the intensive components H and Z (rounded off to the nT) were computed using the relations:

$$H = F \cdot \cos I$$

$$Z = F \cdot \sin I$$

## H<sub>0</sub> and D<sub>0</sub> reference values computation

Since the fluxgate was magnetically oriented in the horizontal plane, as in the previous installations, it was necessary to compute H<sub>0</sub> and D<sub>0</sub> reference values, comparing absolute and relative measurements, at the same time. For the Z component, once the vertical levelling of the sensor was assured, it was assumed that the variations measured by fluxgate were actually the vertical component of the geomagnetic field variations.

In the description the mathematical procedure used for computation of H<sub>0</sub> and D<sub>0</sub>, the following symbols are used:

H <sub>0</sub> , D <sub>0</sub>	Reference values
H <sub>abs</sub> , D <sub>abs</sub>	Values of absolute measurements at time t
x,y	Instantaneous variations recorded by fluxgate system at time t

For each absolute measurement, the reference values were computed as:

$$H_0 = H_{abs} \cos(\varphi) - x$$

$$D_0 = D_{abs} - \varphi$$

where

$$\varphi = \arcsin(y/H_{abs})$$

In order to reduce this dispersion in the set, the Chauvenet criterion was used. The method, based on the hypothesis of a Gauss probability distribution for the data, consists in the elimination of measurements whose difference from the average is greater than a multiple of the standard deviation fixed by the sample dimension (in this case a value 2.4  $\delta$ , corresponding to a sample of 33 data elements, was used).

This method, however, cannot be applied more than once, since an iterative procedure could exclude most of the values up to the complete elimination of the data (Worthing and Jeffner, 1943). The average values of H<sub>0</sub> and D<sub>0</sub> are:

$$H_0 = (7856 \pm 8) \text{ nT}$$
$$D_0 = (138.20 \pm 0.07) \text{ deg}$$

These values are considerably different from those reported in the previous yearbooks because a different instrument was used for the measurements of the instantaneous variations (please refer to the Introduction for more details).

## Daily base lines computation

After H<sub>0</sub> and D<sub>0</sub> reference values are found, the computation of the base lines in relation to absolute measurements and then the computation of the daily base lines for all days, can follow. The available data are the H, D and Z magnetic element variations recorded by fluxgate system (sampling rate 1 minute) and the absolute measurements recorded from Nov 9, 2003, to Dec 3, 2003.

The base lines computation was undertaken by two different procedures. In the case of Z, assuming that the fluxgate recordings show the variations of the vertical components, the base line ( $B_Z$ ) was computed as the difference between the absolute measurements ( $Z_{abs}$ ) and the fluxgate measurements (z). On the other hand, in the case of H and D, the magnetic orientation of the fluxgate system axes was taken into account. Using  $H_0$  and  $D_0$  reference values, the H and D base lines were computed for each absolute measurement as:

$$B_H = H_{abs} - [(H_0+x)^2 + y^2]^{1/2}$$
$$B_D = D_{abs} - D_0 - \arctg[y/(x+H_0)]$$

Mean daily values of the base lines were obtained for those days in which more than one absolute measurement was available.

In order to have a daily base line for each magnetic element, a linear regression analysis using the least squares method has been undertaken. The results are shown in Fig. 1, where the experimental data, as well as the best fit lines are reported.

Using the daily base lines, one minute values for the three field elements H, D and Z were computed as:

$$H = [(H_0+x)^2 + y^2]^{1/2} + B_H$$
$$D = D_0 + \arctg[y/(x+H_0)] + B_D$$
$$Z = z + B_Z$$

Following the Observatory move in 2001/2002 to the new site at OASI, the measurements are reduced to the old site subtracting the following gradient:

$$\Delta H = -1.5 \text{ nT}$$
$$\Delta D = 13.0'$$
$$\Delta Z = 0.7 \text{ nT}$$

In Tables 2, 3, 4 all the hourly and daily averages and the total mean values for the H, D and Z elements on the entire measuring period (from Nov 9, 2003 to Dec 3, 2004) are reported; the relative plots are shown in Fig. 2. The plots of the one minute data follow in succession.

## Geomagnetic Observation Results 2004-2005

### Terra Nova Bay - Antarctica

#### **Introduction**

During 2004 the Italian Base name was changed from Terra Nova Bay to Mario Zucchelli Station; however the international code of the Geomagnetic Observatory is still TNB.

This report deals with activities undertaken at the Antarctic Italian Geomagnetic Observatory during the austral summer 2004-2005.

The coordinates of the Observatory at OASI are the following:

Geographic latitude:	74.6936°S
Geographic longitude:	164.0975°E
Corrected Geomagnetic latitude (IGRF05):	79.97°S
Corrected Geomagnetic longitude (IGRF05):	306.82°E
Magnetic local time midnight:	08:12 UT

This report describes the activities performed from October 30, 2004 to December 3, 2005.

For the present work H, D and Z INTERMAGNET formatted data from the fluxgate magnetometer have been used.

The proton precession magnetometers used to record F total values were Overhauser type; for a description of instruments we refer to geomagnetism text books, for example Parkinson (1983) and Wienert (1970).

Since the total intensity F time variations, at polar latitudes, where values of inclination is almost 90°, are very close to the vertical component Z time variations, the plots of total intensity time variations are not shown. They can however be obtained from the well known equation:

$$F^2 = H^2 + Z^2$$

#### **Absolute measurements**

For the normal absolute measurements-taking at the Observatory, a standard fluxgate magnetometer theodolite for the determination of D, I angles has been used.

At OASI three different azimuth marks are available, for the computation of the Declination (please refer to the 2001/2002 report for details). The coordinates of geodetic points (mark piers and measuring location) were established on the basis of GPS measurements. From these coordinates the azimuth values 152° 44' 04", 60° 13' 36" and 338° 07' 59" were found.

The proton magnetometer recordings, continuously undertaken during the execution of the DI measurements, have allowed the calculation of the absolute intensive elements.

Table 1 shows absolute measurement values for each element; the values of the intensive components H and Z (rounded off to the nT) were computed using the relations:

$$H = F \cdot \cos I$$

$$Z = F \cdot \sin I$$

## H<sub>0</sub> and D<sub>0</sub> reference values computation

Since the fluxgate was magnetically oriented in the horizontal plane, as in the previous installations, it was necessary to compute H<sub>0</sub> and D<sub>0</sub> reference values, comparing absolute and relative measurements, at the same time. For the Z component, once the vertical levelling of the sensor was assured, it was assumed that the variations measured by fluxgate were actually the vertical component of the geomagnetic field variations.

In the description the mathematical procedure used for computation of H<sub>0</sub> and D<sub>0</sub>, the following symbols are used:

H <sub>0</sub> , D <sub>0</sub>	Reference values
H <sub>abs</sub> , D <sub>abs</sub>	Values of absolute measurements at time t
x,y	Instantaneous variations recorded by fluxgate system at time t

For each absolute measurement, the reference values were computed as:

$$H_0 = H_{abs} \cos(\varphi) - x$$

$$D_0 = D_{abs} - \varphi$$

where

$$\varphi = \arcsin(y/H_{abs})$$

In order to reduce this dispersion in the set, the Chauvenet criterion was used. The method, based on the hypothesis of a Gauss probability distribution for the data, consists in the elimination of measurements whose difference from the average is greater than a multiple of the standard deviation fixed by the sample dimension (in this case a value 2.74 σ, corresponding to a sample of about 82 data elements, was used). This method, however, cannot be applied more than once, since an iterative procedure could exclude most of the values up to the complete elimination of the data (Worthing and Jeffner, 1943).

The average values of H<sub>0</sub> and D<sub>0</sub> are:

$$H_0 = (7853 \pm 8) \text{ nT}$$

$$D_0 = (138.34 \pm 0.07) \text{ deg}$$

These values are considerably different from those reported in the previous yearbooks because a different instrument was used for the measurements of the instantaneous variations (please refer to the Introduction for more details).

## Daily base lines computation

After H<sub>0</sub> and D<sub>0</sub> reference values are found, the computation of the base lines in relation to absolute measurements and then the computation of the daily base lines for all days, can follow. The available data are the H, D and Z magnetic element variations recorded by fluxgate system

**TOTAL MEAN = 63697 nT**

## Figure Captions

**Fig 1:** Scatter plot and linear regression for daily H, D and Z<sup>1</sup> base lines.

**Fig 2:** Hourly means of the H, D and Z<sup>1</sup> elements during the whole campaign.

**Fig. 3 – 38:** Daily plots of the one minute values of the H, D and Z<sup>1</sup> elements.

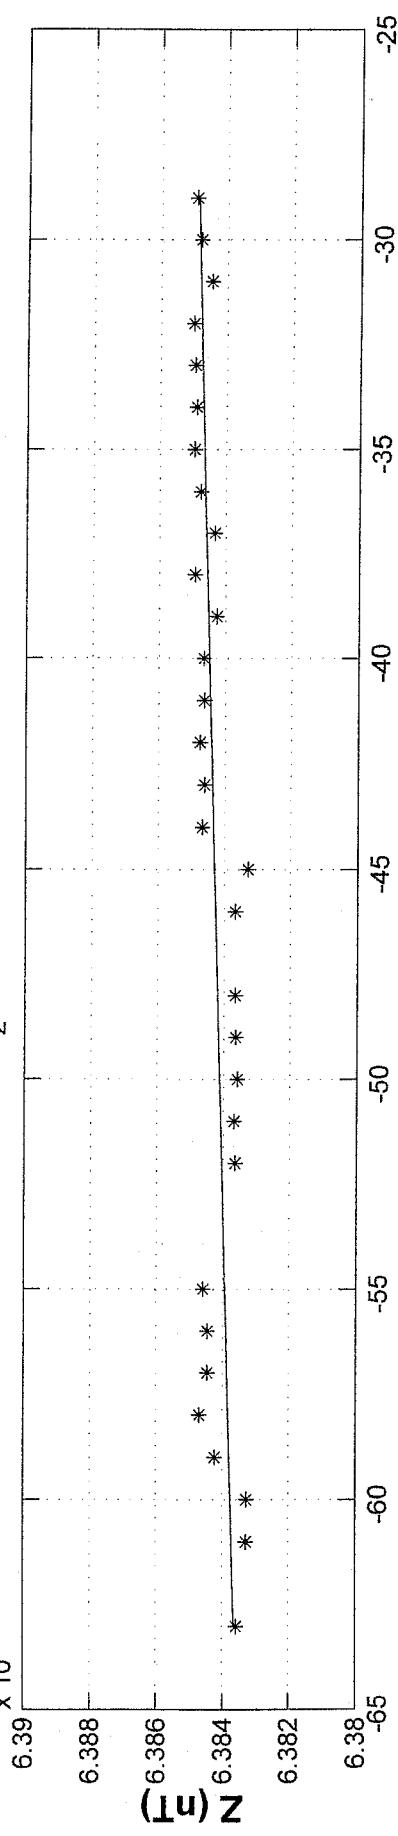

**Fig. 39:** Geomagnetic field trend since 1987.
